

ABSTRACT

A transaction system (104, 144) includes a customer station (116, 146) and a service provider station (112, 148). Items such as medical items, are passed between the service provider and the customer station through item transport devices (118, 154). An enclosure (10) positioned at the customer station houses a payment terminal (16) therein. A movable cover (14) is moved responsive to inputs to a remote control device (36) at the service provider station to enable a customer at the customer station to access the payment terminal. Through inputs to the payment terminal, the customer is enabled to make payment for items that are provided to the customer by the service provider.
